3.4.7 BFGS Method

In the BFGS method, the Hessian is approximated using the variable metric matrix [*A*] given by the equation

$$[A]_{i+1} = [A]_i + \frac{g\nabla g^T}{\nabla g^T \Delta x} + \frac{\nabla f(x_i)\nabla f(x_i)^T}{\nabla f(x_i)^T S_i}$$
(3.28)

It is important to note that whereas the matrix [A] converges to the inverse of the Hessian in the DFP method, the matrix [A] converges to the Hessian itself in the BFGS method. As the BFGS method needs fewer restarts as compared to the DFP method, it is more popular than the DFP method. The algorithm for the BFGS method is described in Table 3.8 and a MATLAB code of its implementation is given in *BFGS.m*.

On executing the code with a starting value of x as (–3, 2) the following output is displayed in the command window for the test problem. Again, it is observed that in the second and third iterations, search points are similar to this method as compared to DFP and the conjugate gradient methods, indicating that search directions were similar. Further, on typing A in the

TABLE 3.8

Algorithm for the BFGS Method

```
Step 1: Given x_i (starting value of design variable)
           \varepsilon_1 (tolerance of function value from previous iteration)
           \varepsilon_2 (tolerance on gradient value)
            \Delta x (required for gradient computation)
           [A] (initialize to identity matrix)
Step 2: Compute f(x_i) and \nabla f(x_i) (function and gradient vector)
           S_i = -\nabla f(\mathbf{x}_i)
                                                (search direction)
           \mathbf{x}_{i+1} = \mathbf{x}_i + \alpha \mathbf{S}_i
                                                (update the design vector)
           Minimize f(x_{i+1}) and determine \alpha (use golden section method)
Step 3: Compute \Delta x and \nabla g
                                                                                                                                     Vg VgT
           [A]_{i+1} = [A]_i + \frac{g\nabla g^T}{\nabla g^T \Delta x} + \frac{\nabla f(x_i)\nabla f(x_i)^T}{\nabla f(x_i)^T S_i}
           S_{i+1} = -[[A]_{i+1}]^{-1} \nabla f(x_{i+1})
           \boldsymbol{x}_{i+2} = \boldsymbol{x}_{i+1} + \alpha \boldsymbol{S}_{i+1}
           Minimize f(x_{i+2}) and determine \alpha (use the golden section method)
           \begin{array}{ll} \text{If} \left| f(x_{i+2}) - f(x_{i+1}) \right| > \varepsilon_1 \text{ or } \|\nabla f(x_{i+1})\| > \varepsilon_2 \\ \text{then} & \text{goto Step 3} \end{array}
                                goto Step 4
                else
Step 4: Converged. Print x^* = x_{i+2}, f(x^*) = f(x_{i+2})
```

MATLAB command prompt and then printing the Hessian matrix at the converged value of x, it is observed that [A] approaches [H].
